SLUSCJ4 -JUNE 2017

# bg25600 and bg25600D I<sup>2</sup>C Controlled 3.0-A, Single Cell Battery Charger With up-to 40-V Overvoltage Protection Controller for High-Input Voltage and Narrow Voltage DC (NVDC) Power Path Management

#### **Features**

- High-Efficiency, 1.5-MHz, Synchronous Switch-Mode Buck Charger
  - 92% Charge Efficiency at 2 A from 5-V Input
  - Optimized for USB Voltage Input (5 V)
  - Selectable Low Power Pulse Frequency Modulation (PFM) Mode for Light Load Operations
- Supports USB On-The-Go (OTG)
  - Boost Converter With Up to 1.2-A Output
  - 92% Boost Efficiency at 1-A Output
  - Accurate Constant Current (CC) Limit
  - Soft-Start Up To 500-µF Capacitive Load
  - Output Short Circuit Protection
  - Selectable Low Power PFM Mode for Light **Load Operations**
- Single Input to Support USB Input and High Voltage Adapters
  - Support 3.9-V to 13.5-V Input Voltage Range With 22-V Absolute Maximum Input Voltage
  - Programmable Input Current Limit (100 mA to 3.2 A With 100-mA Resolution) to Support USB 2.0, USB 3.0 Standards and High Voltage Adaptors (IINDPM)
  - Maximum Power Tracking by Input Voltage Limit Up to 5.4 V (VINDPM)
  - VINDPM Threshold Automatically Tracks **Battery Voltage**
  - Auto Detect USB SDP, DCP and Non-Standard Adaptors
- 200nS Fast Turn-Off of Optional External OVPFET Standing Input Voltage Up to 40V
- High Battery Discharge Efficiency With 19.5-m $\Omega$ Battery Discharge MOSFET
- Narrow VDC (NVDC) Power Path Management
  - Instant-On Works with No Battery or Deeply **Discharged Battery**
  - Ideal Diode Operation in Battery Supplement
- BATFET Control to Support Ship Mode, Wake Up and Full System Reset
- Flexible Autonomous and I<sup>2</sup>C Mode for Optimal System Performance

- High Integration Includes All MOSFETs, Current Sensing and Loop Compensation
- 17-µA Low Battery Leakage Current
- **High Accuracy** 
  - ±0.5% Charge Voltage Regulation
  - ±6% at 1.38-A Charge Current Regulation
  - ±10% at 0.9-A Input Current Regulation
  - Remote Battery Sensing for Fast Charge
- Create a Custom Design Using the bg25600 and bg25600D With the WEBENCH® Power Designer

# Applications

- **Smart Phones**
- Portable Internet Devices and Accessory

# Description

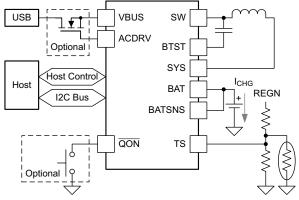

The bq25600 and bq25600D device are a highlyintegrated 3.0-A switch-mode battery management and system power path management device for single cell Li-lon and Li-polymer battery. The low impedance power path optimizes switchmode operation efficiency, reduces battery charging time and extends battery life during discharging phase. The I2C serial interface with charging and system settings makes the device a truly flexible solution.

## Device Information<sup>(1)</sup>

# 4 Description (continued)

The bq25600 and bq25600D are highly-integrated 3.0-A switch-mode battery charge management and system power path management device for single cell Li-Ion and Li-polymer battery. It features fast charging with high input voltage support for a wide range of smart phones, tablets and portable devices. Its low impedance power path optimizes switch-mode operation efficiency, reduces battery charging time and extends battery life during discharging phase. Its input voltage and current regulation and battery remote sensing deliver maximum charging power to battery. The solution is highly integrated with input reverse-blocking FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4) between system and battery. It also integrates the bootstrap diode for the high-side gate drive for simplified system design. The I<sup>2</sup>C serial interface with charging and system settings makes the device a truly flexible solution.

The device supports a wide range of input sources, including standard USB host port, USB charging port, and USB compliant high voltage adapter. The device sets default input current limit based on the built-in USB interface. To set the default input current limit, the device uses the built-in USB interface, or takes the result from detection circuit in the system, such as USB PHY device. The device is compliant with USB 2.0 and USB 3.0 power spec with input current and voltage regulation. The device also meets USB On-the-Go (OTG) operation power rating specification by supplying 5.15 V on VBUS with constant current limit up to 1.2-A.

The power path management regulates the system slightly above battery voltage but does not drop below 3.5 V minimum system voltage (programmable). With this feature, the system maintains operation even when the battery is completely depleted or removed. When the input current limit or voltage limit is reached, the power path management automatically reduces the charge current to zero. As the system load continues to increase, the power path discharges the battery until the system power requirement is met. This Supplement Mode prevents overloading the input source.

The device initiates and completes a charging cycle without software control. It senses the battery voltage and charges the battery in three phases; pre-conditioning, constant current and constant voltage. At the end of the charging cycle, the charger automatically terminates when the charge current is below a preset limit and the battery voltage is higher than recharge threshold. If the fully charged battery falls below the recharge threshold, the charger automatically starts another charging cycle.

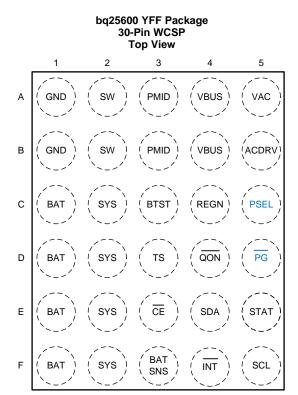

The charger provides various safety features for battery charging and system operations, including battery negative temperature coefficient thermistor monitoring, charging safety timer and overvoltage and overcurrent protections. The thermal regulation reduces charge current when the junction temperature exceeds 110°C (programmable). The STAT output reports the charging status and any fault conditions. Other safety features include battery temperature sensing for charge and boost mode, thermal regulation and thermal shutdown and input UVLO and overvoltage protection. The VBUS\_GD bit indicates if a good power source is present. The INT output Immediately notifies host when fault occurs.

The device also provides QON pin for BATFET enable and reset control to exit low power ship mode or full system reset function.

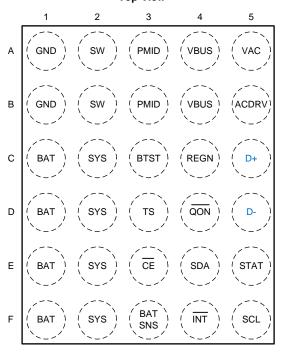

The device family is available in 30-ball, 2.0 mm × 2.4 mm WCSP package.

## **Pin Functions**

	Pin		-	7in Functions		
	bq25600	bq25600D	TYPE <sup>(1)</sup>	DESCRIPTION		
NAME	WCSP	WCSP				
ACDRV	B5	B5	AO	Charge pump output to drive external N-channel MOSFET (OVPFET). ACDRV voltage is 6 V above VBUS when VAC voltage is below ACOV threshold (REG06[6:5]) and above UVLO.		
	C1	C1				
BAT	D1	D1	Р	Battery connection point to the positive terminal of the battery pack. The internal current sensing resistor is connected between SYS and BAT. Connect a 10 µF closely		
DAT	E1	E1	Г	to the BAT pin.		
	F1	F1				
BATSNS	F3	F3	AIO	Battery voltage sensing pin for charge current regulation. in order to minimize the parasitic trace resistance during charging, BATSNS pin is connected to the actual battery pack as close as possible.		
BTST	C3	C3	Р	PWM high side driver positive supply. internally, the BTST is connected to the cathode of the boost-strap diode. Connect the $0.047$ - $\mu$ F bootstrap capacitor from SW to BTST.		
CE	E3	E3	DI	Charge enable pin. When this pin is driven low, battery charging is enabled.		
D+	_	C5	AIO	Positive line of the USB data line pair. D+/D- based USB host/charging port detection. The detection includes data contact detection (DCD), primary and secondary detection in BC1.2.		
D-	_	D5	AIO	Negative line of the USB data line pair. D+/D- based USB host/charging port detection. The detection includes data contact detection (DCD), primary and secondary detection in BC1.2.		
GND	A1	A1				
GND	B1	B1				
ĪNT	F4	F4	DO	Open-drain interrupt Output. Connect the INT to a logic rail through 10-k $\Omega$ resistor. The INT pin sends active low, 256- $\mu$ s pulse to host to report charger device status and fault.		
PG	D5	_	DO	Open drain active low power good indicator. Connect to the pull up rail through 10 k $\Omega$ resistor. LOW indicates a good input source if the input voltage is between UVLO and ACOV, above SLEEP mode threshold, and current limit is above 30 mA.		
	А3	A3		Connected to the drain of the reverse blocking MOSFET (RBFET) and the drain of		
PMID	В3	B3	DO	HSFET. Given the total input capacitance, put 1 $\mu F$ on VBUS to GND, and the rest capacitance on PMID to GND.		
PSEL	C5	_	DI	Power source selection input. High indicates 500 mA input current limit. Low indicates 2.4A input current limit. Once the device gets into host mode, the host can program different input current limit to IINDPM register.		
QON	D4	D4	DI	BATFET enable/reset control input. When BATFET is in ship mode, a logic low of $t_{\text{SHIPMODE}}$ duration turns on BATFET to exit shipping mode. When VBUS is not plugged—in, a logic low of $t_{\text{QON\_RST}}$ (minimum 8 s) duration resets SYS (system power) by turning BATFET off for $t_{\text{BATFET\_RST}}$ (minimum 250 ms) and then re-enable BATFET to provide full system power reset. The pin contains an internal pull-up to maintain default high logic.		
REGN	C4	C4	Р	PWM low side driver positive supply output. internally, REGN is connected to the anode of the boost-strap diode. Connect a 4.7- $\mu$ F (10-V rating) ceramic capacitor from REGN to analog GND. The capacitor should be placed close to the IC.		
SCL	F5	F5	DI	$I^2C$ interface clock. Connect SCL to the logic rail through a 10-k $\Omega$ resistor.		
SDA	E4	E4	DIO	${ m I}^2{ m C}$ interface data. Connect SDA to the logic rail through a 10-k $\Omega$ resistor.		
STAT	E5	E5	DO	Open-drain interrupt output. Connect the STAT pin to a logic rail via 10-k $\Omega$ resistor. The STAT pin indicates charger status. Charge in progress: LOW Charge complete or charger in SLEEP mode: HIGH Charge suspend (fault response): Blink at 1Hz		
	A2	A2		Switching node connecting to output inductor. Internally SW is connected to the source		
SW	B2	B2	Р	of the n-channel HSFET and the drain of the n-channel LSFET. Connect the 0.047-μF bootstrap capacitor from SW to BTST.		
	C2	C2				
	D2	D2	_	Converter output connection point. The internal current sensing resistor is connected		
SYS	E2	E2	Р	between SYS and BAT. Connect a 20 µF closely to the SYS pin.		
	F2	F2				

<sup>(1)</sup> Al = Analog input, AO = Analog Output, AIO = Analog input Output, DI = Digital input, DO = Digital Output, DIO = Digital input Output, P = Power

# Pin Functions (continued)

Pin					
NAME	bq25600	bq25600D	TYPE <sup>(1)</sup>	DESCRIPTION	
NAIVIE	WCSP	WCSP			
Thermal Pad	_	_	Р	Ground reference for the device that is also the thermal pad used to conduct heat from the device. This connection serves two purposes. The first purpose is to provide an electrical ground connection for the device. The second purpose is to provide a low thermal-impedance path from the device die to the PCB. This pad should be tied externally to a ground plane.	
TS	D3	D3	AI	Temperature qualification voltage input to support JEITA profile. Connect a negative temperature coefficient thermistor. Program temperature window with a resistor divider from REGN to TS to GND. Charge suspends when TS pin voltage is out of range. When TS pin is not used, connect a $10\text{-k}\Omega$ resistor from REGN to TS and a $10\text{-k}\Omega$ resistor from TS to GND. It is recommended to use a $103\text{AT-}2$ thermistor.	
VAC	A5	A5	AI	Input voltage sensing. When VAC voltage is below ACOV threshold (REG06[6:5]) and above UVLO, external OVPFET turns on.	
	A4	A4	_	Charger input voltage. The internal n-channel reverse block MOSFET (RBFET) is	
VBUS	B4	B4	Р	connected between VBUS and PMID with VBUS on source. Place a 1-uF ceramic capacitor from VBUS to GND and place it as close as possible to IC.

<sup>(1)</sup> Stresses beyond those listed under Absolute maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. All voltage values are with respect to the network ground terminal unless otherwise noted.

(2) VBUS is specified up to 22 V for a maximum of 1 hour at room temperature

# 6.2 ESD Ratings

			VALUE	UNIT
V <sub>(ESD)</sub> Elec	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins <sup>(1)</sup>	±2000	
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins (2)	±250	V

<sup>(1)</sup> JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

#### 6.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
V <sub>BUS</sub>	Input voltage	3.9		13.5 <sup>(1)</sup>	V
I <sub>in</sub>	Input current (VBUS)			3.25	Α
I <sub>SWOP</sub>	Output current (SW)			3.25	Α
V <sub>BATOP</sub>	Battery voltage			4.624	V
I <sub>BATOP</sub>	Fast charging current			3.0	Α

<sup>(1)</sup> The inherent switching noise voltage spikes should not exceed the absolute maximum voltage rating on either the BTST or SW pins. A tight layout minimizes switching noise.

Product Folder Links: bq25600 bq25600D

<sup>(2)</sup> JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

# 6.7 Typical Characteristics

# TEXAS INSTRUMENTS

# **Typical Characteristics (continued)**

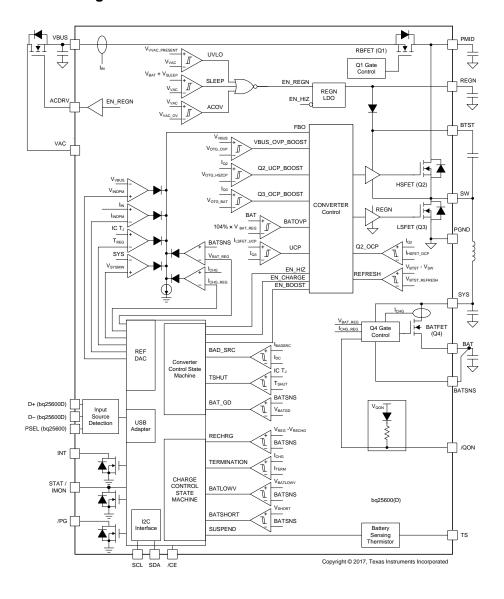

# 7 Detailed Description

## 7.1 Overview

The bq25600 and bq25600D device is a highly integrated 3.0-A switch-mode battery charger for single cell Li-Ion and Li-polymer battery. It includes the input reverse-blocking FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET, Q4), and bootstrap diode for the high-side gate drive.

# 7.2 Functional Block Diagram

# TEXAS INSTRUMENTS

#### 7.3 Feature Description

# 7.3.1 Power-On-Reset (POR)

The device powers internal bias circuits from the higher voltage of VBUS and BAT. When VBUS rises above  $V_{VBUS\_UVLOZ}$  or BAT rises above  $V_{BAT\_UVLOZ}$ , the sleep comparator, battery depletion comparator and BATFET driver are active.  $I^2C$  interface is ready for communication and all the registers are reset to default value. The host can access all the registers after POR.

### 7.3.2 Device Power Up from Battery without Input Source

If only battery is present and the voltage is above depletion threshold (V<sub>BAT\_DPL\_RISE)</sub>, the BATFET turns on and connects battery to system. The REGN stays off to minimize the quiescent current. The low RDSON of BATFET and the low quiescent current on BAT minimize the conduction loss and maximize the battery run time.

The device always monitors the discharge current through BATFET (*Supplement Mode*). When the system is overloaded or shorted ( $I_{BAT} > I_{BATFET\_OCP}$ ), the device turns off BATFET immediately and set BATFET\_DIS bit to indicate BATFET is disabled until the input source plugs in again or one of the methods described in *BATFET Enable* (*Exit Shipping Mode*) is applied to re-enable BATFET.

#### 7.3.3 Power Up from Input Source

When an input source is plugged in, the device checks the input source voltage to turn on REGN LDO and all the bias circuits. It detects and sets the input current limit before the buck converter is started. The power up sequence from input source is as listed:

- 1. Power Up OVPFET
- 2. Power Up REGN LDO
- 3. Poor Source Qualification
- 4. *IInput Source Type Detection is* based on D+/D- or PSEL to set default input current limit (IINDPM) register or input source type.
- 5. Input Voltage Limit Threshold Setting (VINDPM threshold)
- 6. Converter Power-up

#### 7.3.3.1 Power Up OVPFET

The external OVPFET provides an additional layer of voltage protection for the device. The external OVPFET is enabled when all the below conditions are valid.

- VAC above V<sub>VAC\_PRESENT</sub>
- VAC below V<sub>BAT</sub> + V<sub>SLEEP</sub> in boost mode
- VAC below V<sub>VAC OV</sub>
- After t<sub>DEB</sub> (15ms nom.) delay is completed
- OVPFET DIS bit is cleared and EN HIZ bit is cleared

If one of the above conditions is not valid, the device is in high impedance state (HIZ) with REGN LDO off. The device draws less current ( $I_{VBUS\_HIZ}$ ) from VBUS during a HIZ state. The battery powers the system when the device is in a HIZ state.

As shown in Figure 10, V<sub>VAC PRESENT(rising)</sub> < V<sub>VAC</sub> < V<sub>VAC OV(rising)</sub> must be valid before ACDRV goes high.

**Feature Description (continued)** 

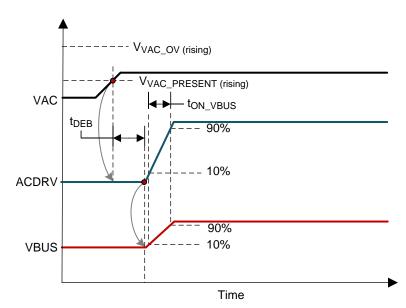

Figure 10. OVPFET Startup Control

## 7.3.3.2 Power Up REGN Regulation

The REGN LDO supplies internal bias circuits as well as the HSFET and LSFET gate drive. The REGN also provides bias rail to TS external resistors. The pull-up rail of STAT can be connected to REGN as well. The REGN is enabled when all the below conditions are valid:

- V<sub>VAC</sub> above V<sub>VAC</sub> PRESENT
- V<sub>VAC</sub> above V<sub>BAT</sub> + V<sub>SLEEPZ</sub> in buck mode or VBUS below V<sub>BAT</sub> + V<sub>SLEEP</sub> in boost mode
- · After 220-ms delay is completed

If any one of the above conditions is not valid, the device is in high impedance mode (HIZ) with REGN LDO off. The device draws less than IVBUS\_HIZ from VBUS during HIZ state. The battery powers up the system when the device is in HIZ.

#### 7.3.3.3 Poor Source Qualification

After REGN LDO powers up, the device confirms the current capability of the input source. The input source must meet both of the following requirements in order to start the buck converter.

- VAC voltage below V<sub>VAC OV</sub>
- VBUS voltage above V<sub>VBUSMIN</sub> when pulling I<sub>BADSRC</sub> (typical 30 mA)

Once the input source passes all the conditions above, the status register bit VBUS\_GD is set high and the INT pin is pulsed to signal to the host. If the device fails the poor source detection, it repeats poor source qualification every 2 seconds.

# 7.3.3.4 Input Source Type Detection

After the VBUS\_GD bit is set and REGN LDO is powered, the device runs input source detection through D+/D-lines or the PSEL pin. The bq25600D follows the USB Battery Charging Specification 1.2 (BC1.2) to detect input source (SDP/ DCP) and non-standard adapter through USB D+/D- lines. The bq25600 sets input current limit through PSEL pins.

After input source type detection is completed, an INT pulse is asserted to the host. in addition, the following registers and pin are changed:

- 1. Input Current Limit (IINDPM) register is changed to set current limit
- 2. PG\_STAT bit is set
- VBUS\_STAT bit is updated to indicate USB or other input source

#### **Feature Description (continued)**

The host can over-write IINDPM register to change the input current limit if needed. The charger input current is always limited by the IINDPM register.

# 7.3.3.4.1 D+/D- Detection Sets Input Current Limit inbq25600D

The bq25600D contains a D+/D- based input source detection to set the input current limit at VBUS plug-in. The D+/D- detection includes standard USB BC1.2 and non-standard adapter. When input source is plugged in, the device starts standard USB BC1.2 detections. The USB BC1.2 is capable to identify Standard Downstream Port (SDP) and Dedicated Charging Port (DCP). When the Data Contact Detection (DCD) timer expires, the non-standard adapter detection is applied to set the input current limit. The non-standard detection is used to distinguish vendor specific adapters (Apple and Samsung) based on their unique dividers on the D+/D- pins. If an adapter is detected as DCP, the input current limit is set at 2.4 A. If an adapter is detected as unknown, the input current limit is set at 0.5 A

**Table 1. Non-Standard Adapter Detection** 

Non-Standard Adapter	D+ Threshold	D- Threshold	Input Current Limit (A)
Divider 1	V <sub>D+</sub> within V <sub>2P7_VTH</sub>	V <sub>D</sub> _ within V <sub>2P0_VTH</sub>	2.1
Divider 2	V <sub>D+</sub> within V <sub>1P2_VTH</sub>	V <sub>D</sub> within V <sub>1P2_VTH</sub>	2
Divider 3	V <sub>D+</sub> within V <sub>2P0_VTH</sub>	V <sub>D</sub> within V <sub>2P7_VTH</sub>	1
Divider 4	V <sub>D+</sub> within V <sub>2P7 VTH</sub>	V <sub>D</sub> within V <sub>2P7 VTH</sub>	2.4

Table 2. Input Current Limit Setting from D+/D- Detection

D+/D- Detection	Input Current Limit (IINLIM)
USB SDP (USB500)	500 mA
USB DCP	2.4 A
Divider 3	1 A
Divider 1	2.1 A
Divider 4	2.4 A
Divider 2	2 A
Unknown 5-V Adapter	500mA

## 7.3.3.4.2 PSEL Pins Sets Input Current Limit in bq25600

The bq25600 has PSEL pin for input current limit setting to interface with USB PHY. It directly takes the USB PHY device output to decide whether the input is USB host or charging port. When the device operates in host-control mode, the host needs to IINDET\_EN bit to read the PSEL value and update the IINDPM register. When the device is in default mode, PSEL value updates IINDPM in real time.

Table 3. Input Current Limit Setting from PSEL

Input Detection	PSEL Pin	INPUT CURRENT LIMIT (ILIM)	VBUS_STAT
USB SDP	High	500 mA	001
Adapter	Low	2.4A	011

## 7.3.3.5 Input Voltage Limit Threshold Setting (VINDPM Threshold)

The device supports wide range of input voltage limit (3.9 V - 5.4V) for USBThe device's VINDPM is set at 4.5V. The device supports dynamic VINDPM trackingsettings which tracks the battery voltage. This function can be enabled via the VDPM\_BAT\_TRACK[1:0] register bits. When enabled, the actual input voltage limit will be the higher of the VINDPM register and VBAT + VDPM BAT\_TRACK offset.

Product Folder Links: bq25600 bq25600D

#### 7.3.3.6 Converter Power-Up

After the input current limit is set, the converter is enabled and the HSFET and LSFET start switching. If battery charging is disabled, BATFET turns off. Otherwise, BATFET stays on to charge the battery.

The device provides soft-start when system rail is ramped up. When the system rail is below 2.2 V, the input current is limited to is to the lower of 200 mA or IINDPM register setting. After the system rises above 2.2 V, the device limits input current to the value set by IINDPM register.

As a battery charger, the device deploys a highly efficient 1.5 MHz step-down switching regulator. The fixed frequency oscillator keeps tight control of the switching frequency under all conditions of input voltage, battery voltage, charge current and temperature, simplifying output filter design.

The device switches to PFM control at light load or when battery is below minimum system voltage setting or charging is disabled. The PFM\_DIS bit can be used to prevent PFM operation in either buck or boost configuration.

#### 7.3.4 Boost Mode Operation From Battery

The device supports boost converter operation to deliver power from the battery to other portable devices through USB port. The boost mode output current rating meets the USB On-The-Go 500 mA output requirement. The maximum output current is up to 1.2 A. The boost operation can be enabled if the conditions are valid:

- 1. BAT above V<sub>OTG BAT</sub>
- 2. VBUS less than BAT+V<sub>SLEEP</sub> (in sleep mode)
- 3. Boost mode operation is enabled (OTG CONFIG bit = 1)
- 4. Voltage at TS (thermistor) pin is within acceptable range (V<sub>BHOT</sub> < V<sub>TS</sub> < V<sub>BCOLD</sub>)
- 5. After 30-ms delay from boost mode enable

During boost mode, the status register VBUS\_STAT bits is set to 111, the VBUS output is 5.15 V and the output current can reach up to 1.2 A, selected through  $I^2C$  (BOOST\_LIM bit). The boost output is maintained when BAT is above  $V_{OTG\ BAT}$  threshold.

When OTG is enabled, the device starts up with PFM and later transits to PWM to minimize the overshoot. The PFM\_DIS bit can be used to prevent PFM operation in either buck or boost configuration.

#### 7.3.5 Host Mode and Standalone Power Management

#### 7.3.5.1 Host Mode and Default Mode in bg25600 and bg25600D

The bq25600 and bq25600D is a host controlled charger, but it can operate in default mode without host management. in default mode, the device can be used as an autonomous charger with no host or while host is in sleep mode. When the charger is in default mode, WATCHDOG\_FAULT bit is HIGH. When the charger is in host mode, WATCHDOG\_FAULT bit is LOW.

After power-on-reset, the device starts in default mode with watchdog timer expired, or default mode. All the registers are in the default settings. During default mode, any change on PSEL pin will make real time IINDPM register changes.

in default mode, the device keeps charging the battery with default 10-hour fast charging safety timer. At the end of the 10-hour, the charging is stopped and the buck converter continues to operate to supply system load.

Writing a 1 to the WD\_RST bit transitions the charger from default mode to host mode. All the device parameters can be programmed by the host. To keep the device in host mode, the host has to reset the watchdog timer by writing 1 to WD\_RST bit before the watchdog timer expires (WATCHDOG\_FAULT bit is set), or disable watchdog timer by setting WATCHDOG bits = 00.

When the watchdog timer expires (WATCHDOG\_FAULT bit = 1), the device returns to default mode and all registers are reset to default values except IINDPM, VINDPM, BATFET\_RST\_EN, BATFET\_DLY, and BATFET\_DIS bits.

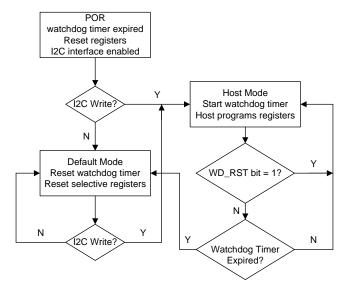

Figure 11. Watchdog Timer Flow Chart

### 7.3.6 Power Path Management

The device accommodates a wide range of input sources from USB, wall adapter, to car charger. The device provides automatic power path selection to supply the system (SYS) from input source (VBUS), battery (BAT), or both.

#### 7.3.7 Battery Charging Management

The device charges 1-cell Li-lon battery with up to 3.0-A charge current for high capacity tablet battery. The 19.5- $m\Omega$  BATFET improves charging efficiency and minimize the voltage drop during discharging.

## 7.3.7.1 Autonomous Charging Cycle

With battery charging is enabled (CHG\_CONFIG bit = 1 and  $\overline{CE}$  pin is LOW), the device autonomously completes a charging cycle without host involvement. The device default charging parameters are listed in Table 4. The host can always control the charging operations and optimize the charging parameters by writing to the corresponding registers through I<sup>2</sup>C.

· · · · · · · · · · · · · · · · · · ·							
Default Mode	bq25600 and bq25600D						
Charging voltage	4.208V						
Charging current	2.048 A						
Pre-charge current	180 mA						
Termination current	180 mA						
Temperature profile	JEITA						
Safety timer	10 hours						

**Table 4. Charging Parameter Default Setting** 

A new charge cycle starts when the following conditions are valid:

- Converter starts
- Battery charging is enabled (CHG\_CONFIG bit = 1 and I<sub>CHG</sub> register is not 0 mA and CE is low)
- No thermistor fault on TS
- No safety timer fault
- BATFET is not forced to turn off (BATFET\_DIS bit = 0)

The charger device automatically terminates the charging cycle when the charging current is below termination threshold, battery voltage is above recharge threshold, and device not is in DPM mode or thermal regulation. When a fully charged battery is discharged below recharge threshold (selectable through VRECHG bit), the device automatically starts a new charging cycle. After the charge is done, toggle  $\overline{\text{CE}}$  pin or CHG\_CONFIG bit can initiate a new charging cycle.

The STAT output indicates the charging status: charging (LOW), charging complete or charge disable (HIGH) or charging fault (Blinking). The STAT output can be disabled by setting EN\_ICHG\_MON bits = 11. in addition, the status register (CHRG\_STAT) indicates the different charging phases: 00-charging disable, 01-precharge, 10-fast charge (constant current) and constant voltage mode, 11-charging done. Once a charging cycle is completed, an INT is asserted to notify the host.

#### 7.3.7.2 Battery Charging Profile

The device charges the battery in five phases: battery short, preconditioning, constant current, constant voltage and top-off trickle charging (optional). At the beginning of a charging cycle, the device checks the battery voltage and regulates current and voltage accordingly.

		• •	
V <sub>BAT</sub>	CHARGING CURRENT	REGISTER DEFAULT SETTING	CHRG_STAT
< 2.2 V	I <sub>SHORT</sub>	100 mA	01
2.2 V to 3 V	I <sub>PRECHG</sub>	180 mA	01
> 3 V	I <sub>CHG</sub>	2.048 A	10

**Table 5. Charging Current Setting** 

If the charger device is in DPM regulation or thermal regulation during charging, the actual charging current will be less than the programmed value. in this case, termination is temporarily disabled and the charging safety timer is counted at half the clock rate.

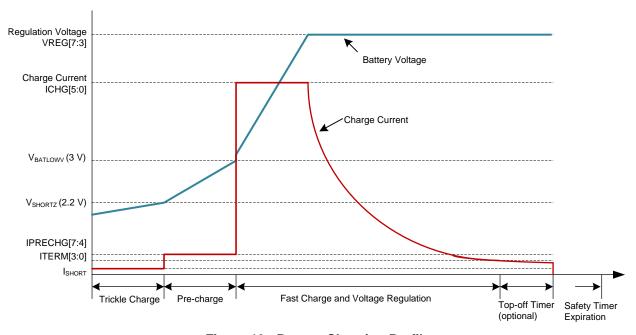

Figure 12. Battery Charging Profile

# 7.3.7.3 Charging Termination

The device terminates a charge cycle when the battery voltage is above recharge threshold, and the current is below termination current. After the charging cycle is completed, the BATFET turns off. The converter keeps running to power the system, and BATFET can turn on again to engage *Supplement Mode*.

When termination occurs, the status register CHRG\_STAT is set to 11, and an INT pulse is asserted to the host. Termination is temporarily disabled when the charger device is in input current, voltage or thermal regulation. Termination can be disabled by writing 0 to EN TERM bit prior to charge termination.

At low termination currents (25 mA-50 mA), due to the comparator offset, the actual termination current may be 10 mA-20 mA higher than the termination target. in order to compensate for comparator offset, a programmable top-off timer can be applied after termination is detected. The termination timer will follow safety timer constraints, such that if safety timer is suspended, so will the termination timer. Similarly, if safety timer is doubled, so will the termination timer. TOPOFF\_ACTIVE bit reports whether the top off timer is active or not. The host can read CHRG\_STAT and TOPOFF\_ACTIVE to find out the termination status.

Top off timer gets reset at one of the following conditions:

- 1. Charge disable to enable
- 2. Termination status low to high
- 3. REG\_RST register bit is set

The top-off timer settings are read in once termination is detected by the charger. Programming a top-off timer value after termination will have no effect unless a recharge cycle is initiated. An INT is asserted to the host when entering top-off timer segment as well as when top-off timer expires.

#### 7.3.7.4 Thermistor Qualification

The charger device provides a single thermistor input for battery temperature monitor.

#### 7.3.7.5 JEITA Guideline Compliance During Charging Mode

To improve the safety of charging Li-ion batteries, JEITA guideline was released on April 20, 2007. The guideline emphasized the importance of avoiding a high charge current and high charge voltage at certain low and high temperature ranges.

To initiate a charge cycle, the voltage on TS pin must be within the VT1 to VT5 thresholds. If TS voltage exceeds the T1-T5 range, the controller suspends charging and waits until the battery temperature is within the T1 to T5 range.

At cool temperature (T1-T2), JEITA recommends the charge current to be reduced to half of the charge current or lower. At warm temperature (T3-T5), JEITA recommends charge voltage less than 4.1 V.

1The charger provides flexible voltage/current settings beyond the JEITA requirement. The voltage setting at warm temperature (T3-T5) can be VREG or 4.1V (configured by JEITA\_VSET). The current setting at cool temperature (T1-T2) can be further reduced to 20% of fast charge current (JEITA\_ISET).

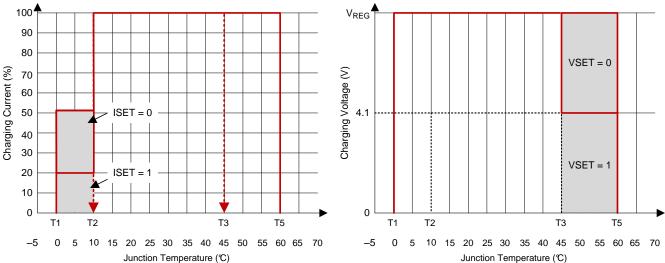

Figure 13. JEITA Profile: Charging Current

Figure 14. JEITA Profile: Charging Voltage

24

Equation 1 through Equation 2 describe updates to the resistor bias network.

$$RT2 = \frac{V_{REGN} \times RTH_{COLD} \times RTH_{HOT} \times \left(\frac{1}{VT1} - \frac{1}{VT5}\right)}{RTH_{HOT} \times \left(\frac{V_{REGN}}{VT5} - 1\right) - RTH_{COLD} \times \left(\frac{V_{REGN}}{VT1} - 1\right)}$$

$$RT1 = \frac{\left(\left(\frac{V_{REGN}}{VT1}\right) - 1\right)}{\left(\frac{1}{RT2}\right) + \left(\frac{1}{RTH_{COLD}}\right)}$$
(2)

Select 0°C to 60°C range for Li-ion or Li-polymer battery:

- RTH<sub>COLD</sub> = 27.28 KΩ
- RTH<sub>HOT</sub> = 3.02 KΩ
- RT1 = 5.23 KΩ
- RT2 = 30.9 KΩ

#### 7.3.7.6 Boost Mode Thermistor Monitor during Battery Discharge Mode

For battery protection during boost mode, the device monitors the battery temperature to be within the VBCOLD to VBHOTthresholds. When temperature is outside of the temperature thresholds, the boost mode is suspended. In additional, VBUS\_STAT bits are set to 000 and NTC\_FAULT is reported. Once temperature returns within thresholds, the boost mode is recovered and NTC\_FAULT is cleared.

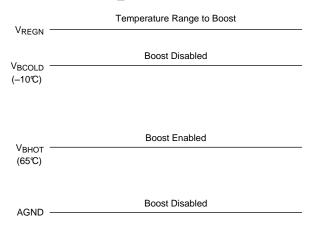

Figure 15. TS Pin Thermistor Sense Threshold in Boost Mode

#### 7.3.7.7 Charging Safety Timer

The device has built-in safety timer to prevent extended charging cycle due to abnormal battery conditions. The safety timer is 2 hours when the battery is below  $V_{BATLOWV}$  threshold and 10 hours when the battery is higher than  $V_{BATLOWV}$  threshold.

The user can program fast charge safety timer through I<sup>2</sup>C (CHG\_TIMER bits). When safety timer expires, the fault register CHRG\_FAULT bits are set to 11 and an INT is asserted to the host. The safety timer feature can be disabled through I<sup>2</sup>C by setting EN\_TIMER bit

During input voltage, current, JEITA cool or thermal regulation, the safety timer counts at half clock rate as the actual charge current is likely to be below the register setting. For example, if the charger is in input current regulation (IDPM\_STAT = 1) throughout the whole charging cycle, and the safety time is set to 5 hours, the safety timer will expire in 10 hours. This half clock rate feature can be disabled by writing 0 to TMR2X\_EN bit.

During the fault, timer is suspended. Once the fault goes away, fault resumes. If user stops the current charging cycle, and start again, timer gets reset (toggle CE pin or CHRG\_CONFIG bit).

# **NSTRUMENTS**

#### 7.3.7.8 Narrow VDC Architecture

The device deploys Narrow VDC architecture (NVDC) with BATFET separating system from battery. The minimum system voltage is set by SYS\_Min bits. Even with a fully depleted battery, the system is regulated above the minimum system voltage.

When the battery is below minimum system voltage setting, the BATFET operates in linear mode (LDO mode), and the system is typically 180 mV above the minimum system voltage setting. As the battery voltage rises above the minimum system voltage, BATFET is fully on and the voltage difference between the system and battery is the VDS of BATFET.

When the battery charging is disabled and above minimum system voltage setting or charging is terminated, the system is always regulated at typically 50mV above battery voltage. The status register VSYS STAT bit goes high when the system is in minimum system voltage regulation.

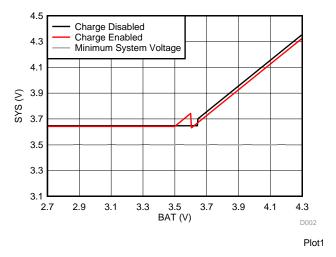

Figure 16. System Voltage vs Battery Voltage

#### 7.3.7.9 Dynamic Power management

To meet maximum current limit in USB spec and avoid over loading the adapter, the device features Dynamic Power management (DPM), which continuously monitors the input current and input voltage. When input source is over-loaded, either the current exceeds the input current limit (IIDPM) or the voltage falls below the input voltage limit (VINDPM). The device then reduces the charge current until the input current falls below the input current limit and the input voltage rises above the input voltage limit.

When the charge current is reduced to zero, but the input source is still overloaded, the system voltage starts to drop. Once the system voltage falls below the battery voltage, the device automatically enters the supplement mode where the BATFET turns on and battery starts discharging so that the system is supported from both the input source and battery.

During DPM mode, the status register bits VDPM\_STAT (VINDPM) or IDPM\_STAT (IINDPM) goes high. Figure 17 shows the DPM response with 9-V/1.2-A adapter, 3.2-V battery, 2.8-A charge current and 3.5-V minimum system voltage setting.

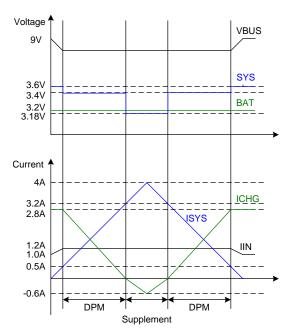

Figure 17. DPM Response

# 7.3.7.10 Supplement Mode

When the system voltage falls 180 mV (VBAT > VSYSMin) or 45 mV (VBAT < VSYSMin) below the battery voltage, the BATFET turns on and the BATFET gate is regulated the gate drive of BATFET so that the minimum BATFET VDS stays at 30 mV when the current is low. This prevents oscillation from entering and exiting the supplement mode.

As the discharge current increases, the BATFET gate is regulated with a higher voltage to reduce RDSON until the BATFET is in full conduction. At this point onwards, the BATFET VDS linearly increases with discharge current. Figure 18 shows the V-I curve of the BATFET gate regulation operation. BATFET turns off to exit supplement mode when the battery is below battery depletion threshold.

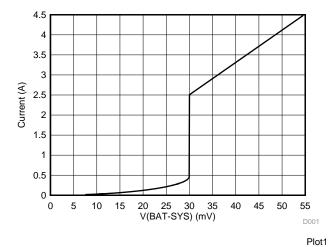

Figure 18. BAFET V-I Curve

# TEXAS INSTRUMENTS

# 7.3.8 Shipping Mode and QON Pin

### 7.3.8.1 BATFET Disable Mode (Shipping Mode)

To extend battery life and minimize power when system is powered off during system idle, shipping, or storage, the device can turn off BATFET so that the system voltage is zero to minimize the battery leakage current. When the host set BATFET\_DIS bit, the charger can turn off BATFET immediately or delay by  $t_{SM\_DLY}$  as configured by BATFET\_DLY bit.

### 7.3.8.2 BATFET Enable (Exit Shipping Mode)

When the BATFET is disabled (in shipping mode) and indicated by setting BATFET\_DIS, one of the following events can enable BATFET to restore system power:

- 1. Plug in adapter
- 2. Clear BATFET DIS bit
- 3. Set REG\_RST bit to reset all registers including BATFET\_DIS bit to default (0)
- A logic high to low transition on QON pin with t<sub>SHIPMODE</sub> deglitch time to enable BATFET to exit shipping mode

# 7.3.8.3 BATFET Full System Reset

The BATFET functions as a load switch between battery and system when input source is not pluggeD–in. By changing the state of BATFET from on to off, systems connected to SYS can be effectively forced to have a power-on-reset. The QON pin supports push-button interface to reset system power without host by changing the state of BATFET.

When the  $\overline{\text{QON}}$  pin is driven to logic low for  $t_{\text{QON\_RST}}$  while input source is not plugged in and BATFET is enabled (BATFET\_DIS = 0), the BATFET is turned off for  $t_{\text{BATFET\_RST}}$  and then it is re-enabled to reset system power. This function can be disabled by setting BATFET\_RST\_EN bit to 0.

#### 7.3.8.4 QON Pin Operations

The QON pin incorporates two functions to control BATFET.

- 1. BATFET Enable: A  $\overline{\text{QON}}$  logic transition from high to low with longer than  $t_{\text{SHIPMODE}}$  deglitch turns on BATFET and exit shipping mode
- 2. BATFET Reset: When  $\overline{\text{QON}}$  is driven to logic low by at least  $t_{\text{QON\_RST}}$  while adapter is not plugged in (and BATFET\_DIS = 0), the BATFET is turned off for  $t_{\text{BATFET\_RST}}$ . The BATFET is re-enabled after  $t_{\text{BATFET\_RST}}$  duration. This function allows systems connected to SYS to have power-on-reset. This function can be disabled by setting BATFET\_RST\_EN bit to 0.

Figure 19 shows the sample external configurations for each.

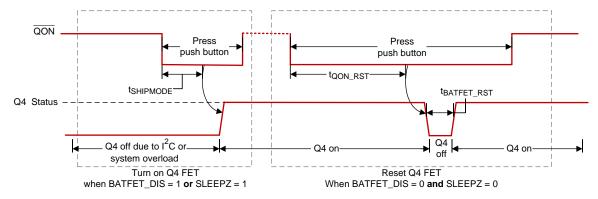

Figure 19. QON Timing

28

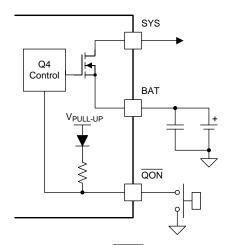

Figure 20. QON Circuit

# 7.3.9 Status Outputs (PG, STAT, INT)

# 7.3.9.1 Power Good indicator (PG Pin and PG\_STAT Bit)

The PG\_STAT bit goes HIGH and PG pin goes LOW to indicate a good input source when:

- VBUS above V<sub>VBUS\_UVLO</sub>
- · VBUS above battery (not in sleep)
- VBUS below V<sub>VAC OV</sub> threshold
- VBUS above V<sub>VBUSMin</sub> (typical 3.8 V) when I<sub>BADSRC</sub> (typical 30 mA) current is applied (not a poor source)
- Completed input Source Type Detection

## 7.3.9.2 Charging Status indicator (STAT)

The device indicates charging state on the open drain STAT pin. The STAT pin can drive LED. The STAT pin function can be disabled by setting the EN\_ICHG\_MON bits = 11.

Table 6. STAT Pin State

CHARGING STATE	STAT INDICATOR
Charging in progress (including recharge)	LOW
Charging complete	HIGH
Sleep mode, charge disable	HIGH
Charge suspend (input overvoltage, TS fault, timer fault or system overvoltage) Boost Mode suspend (due to TS fault)	Blinking at 1 Hz

## 7.3.9.3 Interrupt to Host (INT)

In some applications, the host does not always monitor the charger operation. The INT pulse notifies the system on the device operation. The following events will generate 256-µs INT pulse.

- USB/adapter source identified (through PSEL or DPDM detection)
- Good input source detected
  - VBUS above battery (not in sleep)
  - VBUS below V<sub>VAC OV</sub> threshold
  - VBUS above V<sub>VBUSMin</sub> (typical 3.8 V) when I<sub>BADSRC</sub> (typical 30 mA) current is applied (not a poor source)
- input removed
- Charge Complete
- Any FAULT event in REG09
- VINDPM / IINDPM event detected (maskable)

When a fault occurs, the charger device sends out INT and keeps the fault state in REG09 until the host reads the fault register. Before the host reads REG09 and all the faults are cleared, the charger device would not send any INT upon new faults. To read the current fault status, the host has to read REG09 two times consecutively. The first read reports the pre-existing fault register status and the second read reports the current fault register status.

#### 7.3.10 Protections

#### 7.3.10.1 Voltage and Current Monitoring in Converter Operation

The device closely monitors the input and system voltage, as well as internal FET currents for safe buck and boost mode operation.

#### 7.3.10.1.1 Voltage and Current Monitoring in Buck Mode

#### 7.3.10.1.1.1 Input Overvoltage (ACOV)

This device integrates the functionality of an overvoltage protector. The device can be paired with an external Nchannel FET to block input voltages in excess of VBUS rating. For correct operation, connect the cathode of body diode to VAC node. Back-to-back body diodes between VAC and VBUS are not recommended and will prevent correct operation. The input voltage is sensed via the VAC pin and the ACDRV pin is used to control the external FET gate for protection. The OVP threshold defaults to 6.2V, but can be programmed at 5.5V, 6.2V, 10.5V, or 14.3V via OVP register bits. The ACOV circuit has a reaction time of t<sub>AC OV FLT</sub>. Note that turning off the external OVPFET will take longer and depends on its gate capacitance. In addition to turning off the external FET, an ACOV event will immediately stop switching whether in buck or boost mode.

During input overvoltage event (ACOV), the fault register CHRG FAULT bits are set to 01. An INT pulse is asserted to the host. The device will automatically resume normal operation once the input voltage drops back below the OVP threshold.

#### 7.3.10.1.1.2 System Overvoltage Protection (SYSOVP)

The charger device clamps the system voltage during load transient so that the components connect to system would not be damaged due to high voltage. SYSOVP threshold is 350 mV above minimum system regulation voltage when the system is regulate at V<sub>SYSMIN</sub>. Upon SYSOVP, converter stops switching immediately to clamp the overshoot. The charger provides 30 mA discharge current to bring down the system voltage.

# 7.3.10.2 Voltage and Current Monitoring in Boost Mode

The device closely monitors the VBUS voltage, as well as RBFET and LSFET current to ensure safe boost mode operation.

#### 7.3.10.2.1 VBUS Soft Start

When the boost function is enabled, the device soft-starts boost mode to avoid inrush current.

# 7.3.10.2.2 VBUS Output Protection

The device monitors boost output voltage and other conditions to provide output short circuit and overvoltage protection. The Boost build in accurate constant current regulation to allow OTG to adaptive to various types of load. If short circuit is detected on VBUS, the Boost turns off and retry 7 times. If retries are not successful, OTG is disabled with OTG\_CONFIG bit cleared. In addition, the BOOST\_FAULT bit is set and INT pulse is generated. The BOOST FAULT bit can be cleared by host by re-enabling boost mode

#### 7.3.10.2.3 Boost Mode Overvoltage Protection

When the VBUS voltage rises above regulation target and exceeds VOTG\_OVP, the device enters overvoltage protection which stops switching, clears OTG CONFIG bit and exits boost mode. At Boost overvoltage duration, the fault register bit (BOOST\_FAULT) is set high to indicate fault in boost operation. An INT is also asserted to the host.

#### 7.3.10.3 Thermal Regulation and Thermal Shutdown

#### 7.3.10.3.1 Thermal Protection in Buck Mode

The bq25600 and bq25600D monitors the internal junction temperature  $T_J$  to avoid overheat the chip and limits the IC surface temperature in buck mode. When the internal junction temperature exceeds thermal regulation limit (110°C), the device lowers down the charge current. During thermal regulation, the actual charging current is usually below the programmed battery charging current. Therefore, termination is disabled, the safety timer runs at half the clock rate, and the status register THERM\_STAT bit goes high.

Additionally, the device has thermal shutdown to turn off the converter and BATFET when IC surface temperature exceeds  $T_{SHUT}(160^{\circ}C)$ . The fault register CHRG\_FAULT is set to 1 and an  $\overline{INT}$  is asserted to the host. The BATFET and converter is enabled to recover when IC temperature is  $T_{SHUT\_HYS}$  (30°C) below  $T_{SHUT}(160^{\circ}C)$ .

#### 7.3.10.3.2 Thermal Protection in Boost Mode

The device monitors the internal junction temperature to provide thermal shutdown during boost mode. When IC junction temperature exceeds  $T_{SHUT}$  (160°C), the boost mode is disabled by setting OTG\_CONFIG bit low and BATFET is turned off. When IC junction temperature is below  $T_{SHUT}$  (160°C) -  $T_{SHUT\_HYS}$  (30°C), the BATFET is enabled automatically to allow system to restore and the host can re-enable OTG\_CONFIG bit to recover.

#### 7.3.10.4 Battery Protection

### 7.3.10.4.1 Battery overvoltage Protection (BATOVP)

The battery overvoltage limit is clamped at 4% above the battery regulation voltage. When battery over voltage occurs, the charger device immediately disables charging. The fault register BAT\_FAULT bit goes high and an INT is asserted to the host.

#### 7.3.10.4.2 Battery Over-Discharge Protection

When battery is discharged below  $V_{BAT\_DPL\_FALL}$ , the BATFET is turned off to protect battery from over discharge. To recover from over-discharge latch-off, an input source plug-in is required at VBUS. The battery is charged with  $I_{SHORT}$  (typically 100 mA) current when the VBAT < VSHORT, or precharge current as set in IPRECHG register when the battery voltage is between  $V_{SHORTZ}$  and  $V_{BAT\_LOWV}$ .

## 7.3.10.4.3 System Over-Current Protection

When the system is shorted or significantly overloaded (IBAT > IBATOP) and the current exceeds BATFET overcurrent limit, the BATFET latches off. Section BATFET Enable (Exit Shipping Mode) can reset the latch-off condition and turn on BATFET.

#### 7.3.11 Serial interface

The device uses I<sup>2</sup>C compatible interface for flexible charging parameter programming and instantaneous device status reporting. I<sup>2</sup>CTM is a bi-directional 2-wire serial interface developed by Philips Semiconductor (now NXP Semiconductors). Only two bus lines are required: a serial data line (SDA) and a serial clock line (SCL). Devices can be considered as masters or slaves when performing data transfers. A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

The device operates as a slave device with address 6BH, receiving control inputs from the master device like micro controller or a digital signal processor through REG00-REG0B. Register read beyond REG0B (0x0B) returns 0xFF. The I<sup>2</sup>C interface supports both standard mode (up to 100 kbits), and fast mode (up to 400 kbits). connecting to the positive supply voltage via a current source or pull-up resistor. When the bus is free, both lines are HIGH. The SDA and SCL pins are open drain.

# 7.3.11.1 Data Validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW. One clock pulse is generated for each data bit transferred.

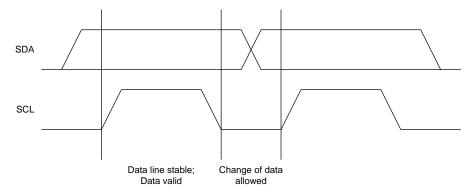

Figure 21. Bit Transfer on the I<sup>2</sup>C Bus

#### 7.3.11.2 START and STOP Conditions

All transactions begin with a START (S) and can be terminated by a STOP (P). A HIGH to LOW transition on the SDA line while SCI is HIGH defines a START condition. A LOW to HIGH transition on the SDA line when the SCL is HIGH defines a STOP condition. START and STOP conditions are always generated by the mAster. The bus is considered busy after the START condition, and free after the STOP condition.

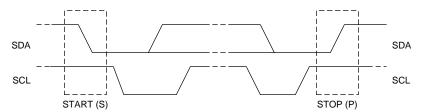

Figure 22. TS START and STOP conditions

## 7.3.11.3 Byte Format

Every byte on the SDA line must be 8 bits long. The number of bytes to be transmitted per transfer is unrestricted. Each byte has to be followed by an Acknowledge bit. Data is transferred with the Most Significant Bit (MSB) first. If a slave cannot receive or transmit another complete byte of data until it has performed some other function, it can hold the clock line SCL low to force the mAster into a wait state (clock stretching). Data transfer then continues when the slave is ready for another byte of data and release the clock line SCL.

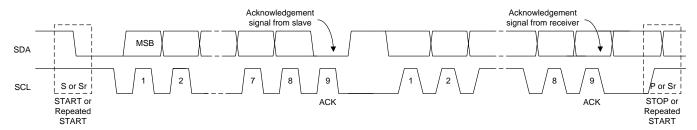

Figure 23. Data Transfer on the I<sup>2</sup>C Bus

# 7.3.11.4 Acknowledge (ACK) and Not Acknowledge (NACK)

The acknowledge takes place after every byte. The acknowledge bit allows the receiver to signal the transmitter that the byte was successfully received and another byte may be sent. All clock pulses, including the acknowledge ninth clock pulse, are generated by the mAster. The transmitter releases the SDA line during the acknowledge clock pulse so the receiver can pull the SDA line LOW and it remains stable LOW during the HIGH period of this clock pulse.

When SDA remains HIGH during the ninth clock pulse, this is the Not Acknowledge signal. The mAster can then generate either a STOP to abort the transfer or a repeated START to start a new transfer.

#### 7.3.11.5 Slave Address and Data Direction Bit

After the START, a slave address is sent. This address is 7 bits long followed by the eighth bit as a data direction bit (bit R/W). A zero indicates a transmission (WRITE) and a one indicates a request for data (READ).

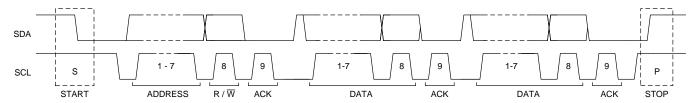

Figure 24. Complete Data Transfer

## 7.3.11.6 Single Read and Write

If the register address is not defined, the charger IC send back NACK and go back to the idle state.

Figure 25. Single Write

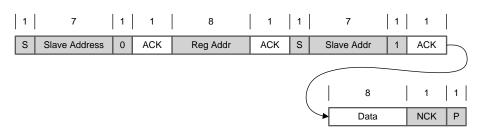

Figure 26. Single Read

## 7.3.11.7 Multi-Read and Multi-Write

The charger device supports multi-read and multi-write on REG00 through REG0B.

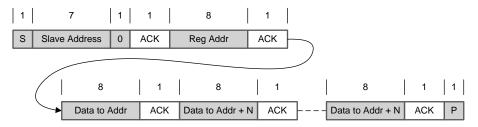

Figure 27. Multi-Write

Figure 28. Multi-Read

Copyright © 2017, Texas Instruments Incorporated

REG09 is a fault register. It keeps all the fault information from last read until the host issues a new read. For example, if Charge Safety Timer Expiration fault occurs but recovers later, the fault register REG09 reports the fault when it is read the first time, but returns to normal when it is read the second time. in order to get the fault information at present, the host has to read REG09 for the second time. The only exception is NTC\_FAULT which always reports the actual condition on the TS pin. in addition, REG09 does not support multi-read and multi-write.

## 8 Application and Implementation

### **NOTE**

information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application information

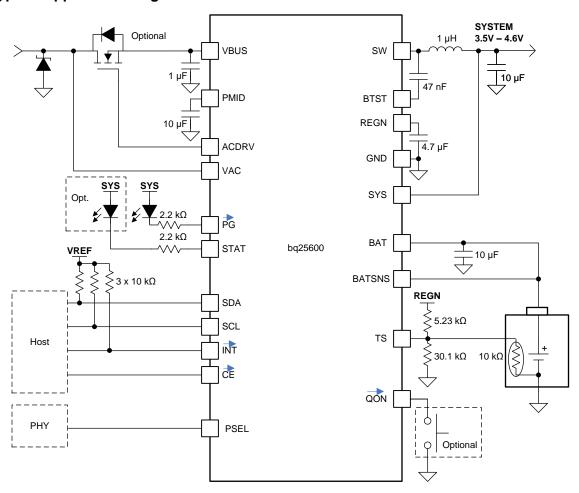

A typical application consists of the device configured as an I<sup>2</sup>C controlled power path management device and a single cell battery charger for Li-lon and Li-polymer batteries used in a wide range of smart phones and other portable devices. It integrates an input reverse-block FET (RBFET, Q1), high-side switching FET (HSFET, Q2), low-side switching FET (LSFET, Q3), and battery FET (BATFET Q4) between the system and battery. The device also integrates a bootstrap diode for the high-side gate drive.

#### **Design Requirements**

### 8.2.2 Detailed Design Procedure

### 8.2.2.1 Custom Design With WEBENCH® Tools

Click here to create a custom design using the bq25600 device with the WEBENCH® Power Designer.

- 1. Start by entering the input voltage (V<sub>IN</sub>), output voltage (V<sub>OUT</sub>), and output current (I<sub>OUT</sub>) requirements.
- 2. Optimize the design for key parameters such as efficiency, footprint, and cost using the optimizer dial.
- 3. Compare the generated design with other possible solutions from Texas Instruments.

The WEBENCH Power Designer provides a customized schematic along with a list of materials with real-time pricing and component availability.

In most cases, these actions are available:

- Run electrical simulations to see important waveforms and circuit performance
- Run thermal simulations to understand board thermal performance
- Export customized schematic and layout into popular CAD formats
- Print PDF reports for the design, and share the design with colleagues

Get more information about WEBENCH tools at www.ti.com/WEBENCH.

### Typical Application Diagram (continued)

#### 8.2.2.2 inductor Selection

The 1.5-MHz switching frequency allows the use of small inductor and capacitor values to maintain an inductor saturation current higher than the charging current ( $I_{CHG}$ ) plus half the ripple current ( $I_{RIPPLE}$ ):

$$I_{SAT} \ge I_{CHG} + (1/2) I_{RIPPLE} \tag{3}$$

The inductor ripple current depends on the input voltage ( $V_{VBUS}$ ), the duty cycle ( $D = V_{BAT}/V_{VBUS}$ ), the switching frequency ( $f_S$ ) and the inductance (L).

$$I_{RIPPLE} = \frac{V_{IN} \times D \times (1 - D)}{fs \times L}$$
(4)

The maximum inductor ripple current occurs when the duty cycle (D) is 0.5 or approximately 0.5. Usually inductor ripple is designed in the range between 20% and 40% maximum charging current as a trade-off between inductor size and efficiency for a practical design.

### 8.2.2.3 input Capacitor

Design input capacitance to provide enough ripple current rating to absorb input switching ripple current. The worst case RMS ripple current is half of the charging current when duty cycle is 0.5. If the converter does not operate at 50% duty cycle, then the worst case capacitor RMS current I<sub>Cin</sub> occurs where the duty cycle is closest to 50% and can be estimated using Equation 5.

$$I_{CIN} = I_{CHG} \times \sqrt{D \times (1 - D)}$$
(5)

Low ESR ceramic capacitor such as X7R or X5R is preferred for input decoupling capacitor and should be placed to the drain of the high-side MOSFET and source of the low-side MOSFET as close as possible. Voltage rating of the capacitor must be higher than normal input voltage level. A rating of 25-V or higher capacitor is preferred for 15 V input voltage. Capacitance of 22-µF is suggested for typical of 3A charging current.

#### 8.2.2.4 Output Capacitor

Ensure that the output capacitance has enough ripple current rating to absorb the output switching ripple current. Equation 6 shows the output capacitor RMS current I<sub>COUT</sub> calculation.

$$I_{COUT} = \frac{I_{RIPPLE}}{2 \times \sqrt{3}} \approx 0.29 \times I_{RIPPLE}$$
(6)

The output capacitor voltage ripple can be calculated as follows:

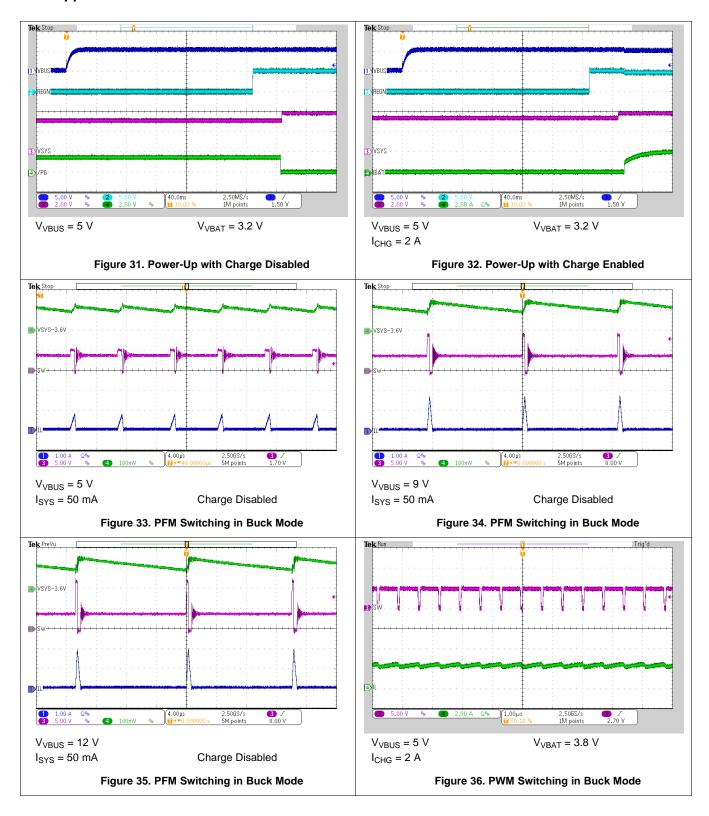

$$\Delta V_{O} = \frac{V_{OUT}}{8LCfs^{2}} \left( 1 - \frac{V_{OUT}}{V_{IN}} \right)$$
(7)

At certain input and output voltage and switching frequency, the voltage ripple can be reduced by increasing the output filter LC.

The charger device has internal loop compensation optimized for >20μF ceramic output capacitance. The preferred ceramic capacitor is 10V rating, X7R or X5R.

## 9 Power Supply Recommendations

in order to provide an output voltage on SYS, the bq25600 and bq25600D device requires a power supply between 3.9 V and 14.2 V input with at least 100-mA current rating connected to VBUS and a single-cell Li-Ion battery with voltage > V<sub>BATUVLO</sub> connected to BAT. The source current rating needs to be at least 3 A in order for the buck converter of the charger to provide maximum output power to SYS.

Submit Documentation Feedback

### 10 Layout

### 10.1 Layout Guidelines

The switching node rise and fall times should be minimized for minimum switching loss. Proper layout of the components to minimize high frequency current path loop (see Figure 51) is important to prevent electrical andmagnetic field radiation and high frequency resonant problems.

### **IMPORTANT**

It is essential to follow this specific layout PCB order.

- 1. Place input capacitor as close as possible to PMID pin and GND pin connections and use shortest copper trace connection or GND plane.
- 2. Put output capacitor near to the inductor and the IC.
- 3. Decoupling capacitors should be placed next to the IC pins and make trace connection as short as possible.
- 4. Place inductor input terminal to SW pin as close as possible. Minimize the copper area of this trace to lower electrical and magnetic field radiation but make the trace wide enough to carry the charging current. Do not use multiple layers in parallel for this connection. Minimize parasitic capacitance from this area to any other trace or plane.
- 5. It is OK to connect all grounds together to reduce PCB size and improve thermal dissipation.
- Try to avoid ground planes in parallel with high frequency traces in other layers.See the EVM design for the recommended component placement with trace and via locations.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead/Ball Finish Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

DIE SIZE BALL GRID ARRAY

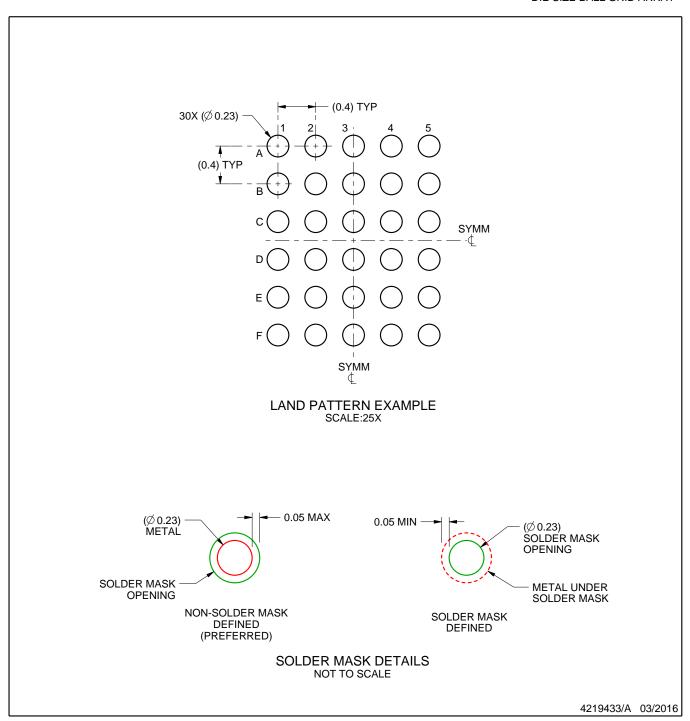

### NOTES:

- All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
- 2. This drawing is subject to change without notice.

DIE SIZE BALL GRID ARRAY

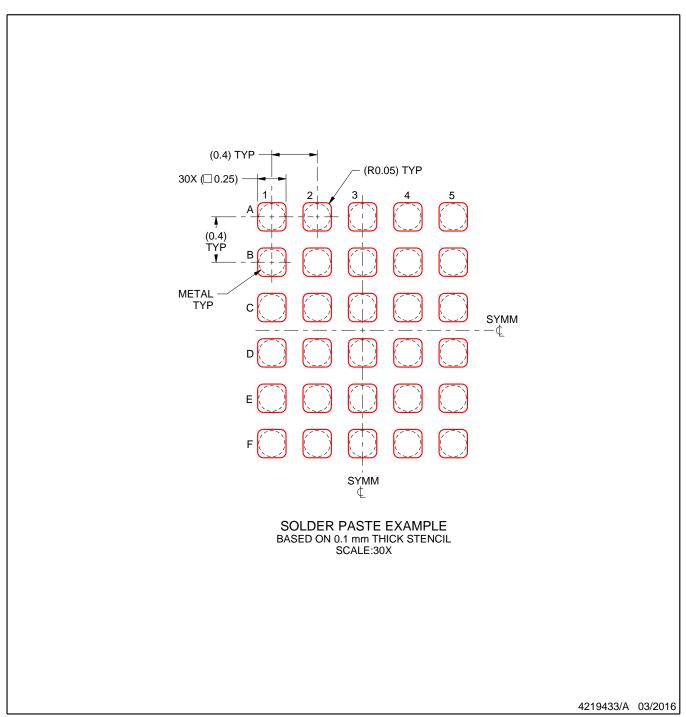

NOTES: (continued)

3. Final dimensions may vary due to manufacturing tolerance considerations and also routing constraints. For more information, see Texas Instruments literature number SNVA009 (www.ti.com/lit/snva009).

DIE SIZE BALL GRID ARRAY

NOTES: (continued)

4. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release.

#### **IMPORTANT NOTICE**

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (http://www.ti.com/sc/docs/stdterms.htm) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
